## 1. Introduction

This report provides summarized results and analysis of the annual game count held on the NamibRand Nature Reserve and the Pro-Namib Conservancy on the 23th of May 2020.

A game count briefing was held at the NamibRand Nature Reserve AGM on the day preceding the count where Control Warden Murray Tindall highlighted the objectives of the count and outlined the methodology and rules for the teams who would conduct the count. This helps to ensure consistency over consecutive years and allows a more accurate comparison from year to year.

Previous years data has been entered into a purpose designed database which generates the estimates used in this report in terms of total population, density and biomass. A few minor adjustments have been made to the database in order to improve its accuracy and this has slightly altered the figures for previous years as well as this years' count.

Surprisingly, even though this is the fifth year of drought the population estimates, as well as the overall density, showed marked increases this year. Individual populations of the two major grazers in this ecosystem, oryx and springbok, showed increases of $60 \%$ and $10 \%$ respectively. Overall, there was a significant increase in the majority of the different species populations this year ( $43 \%$ increase). However, the population of Ruppel's Korhaan was the only population that showed a decrease (36\%).

The distribution of animals across the reserve showed a slight trend of migration towards the northern parts of the NamibRand Nature Reserve. The majority of animals were concentrated near the north of the reserve, in plains/grassland areas (Zones 2, 3 and 4). The highest estimated populations of animals were seen in Zones 2 and 3.

It is worth reiterating that this census method is best suited to large plains game such as oryx, springbok and Burchell's zebra and is less suited to smaller species such as steenbok, or species with different habitat requirements such as kudu or mountain zebra. In addition, the estimates provided are intended to give an indication of population numbers and enable a comparison from year to year and may not be an entirely accurate reflection of the actual number of animals on the Reserve.

Please note that while the game count method employed is good for estimating larger numbers of common plains game, it less suited for other species such as kudu and steenbok. No single census method is complete in itself, but needs to be supplemented and complemented on a dynamic basis by local knowledge and other sources of information, e.g. independent total counts of recently re-introduced species, incidental sightings and camera trap recordings.

## 2. Summary

Data collected in the May 2020 game count was entered into our database and analyzed.
The below results give a summary of all animals counted, this includes animals seen further than 500 m .
Table 1. Total number of game seen on the count for May 2020.

| Mammals |  | Carnivores |  | Birds |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Giraffe | 3 | Bat-eared Fox | 23 | Greater Kestrel | 2 |
| Hartebeest | 1 | Black-backed Jackel | 5 | Lappet-faced Vulture | 11 |
| Gemsbok | 561 |  |  | Ludwig Bustard | 10 |
| Burchell Zebra | 152 |  |  | Ostrich | 83 |
| Springbok | 585 |  |  | Rüppel Korhaan | 15 |

The results below give you the total of species counted per route, this includes animals seen above 500 m .
Table 2. Total number of game seen on each route for May 2020.

| Total species counted per route |  |
| ---: | ---: |
| 1 | 16 |
| 2 | 155 |
| 3 | 354 |
| 4 | 8 |
| 5 | 34 |
| 6 | 198 |
| 7 | 320 |
| 8 | 72 |
| 9 | $\mathbf{2 6 9}$ |
| 10 | 25 |

The below table give you the total species per route seen under or by 500 m . This is the amount we use to do the calculation for the rest of the document.

Table 3. Total number of game seen on each route less than 500m for May 2020.

| Total species counted per route less than 500 |  |
| ---: | ---: |
| 1 | 15 |
| 2 | 142 |
| 3 | 354 |
| 4 | 8 |
| 5 | 35 |
| 6 | 182 |
| 7 | 320 |
| 8 | 75 |
| 9 | 269 |
| 10 | 25 |

The results shown below are bearing our three core objectives in mind:

## Objective 1: Population and biomass estimates:

## Population estimates:

Table 4. Total number of game seen and the estimated numbers for May 2020.

| Total estimated numbers of game (Zone 1-10; May 2020) |  |  |
| :--- | ---: | ---: |
| Species | No. Counted | Estimate 2020 |
| Gemsbok | 552 | 6758 |

| * Total (estimate) numbers known |  |  |  |  |  |

## 3. Count Methodology

The primary objectives of the game count are to determine the density and distribution of game and to estimate the total number of game in a given, or total, area. For this reason, the survey methodology used is a combination of the road strip census and game distribution map techniques. In layman's terms, these can be explained as follows:

## Road strip count

This is one of the most effective methods to use when counting in a relatively open and homogenous landscape. For the purposes of the count, the total area is divided into game count zones, each with its own standardized route, as shown in Figure 1 on the next page. The game count zones were, as far as possible, deliberately predetermined into homogenous habitats because the visibility of animals differs in each habitat. Each route forms a strip transect through its zone within which the animals are counted. A transect width of 1 km is used ( 500 m on either side of the road). During the count, all animals on either side of the road are recorded, and the distances (at right angles to the vehicle and road) from the road to the animal or group of animals is recorded. These distance records are important, as they shape the effective strip width (ESW) values, which are automatically adjusted each year when data is entered into the database.
The length of the transect (distance traveled) and its relation to the area represented in the zone is used to calculate the area correction factors for each zone, i.e. area represented/route length = area correction factor. The respective effective strip width (ESW) values and transect width then determines the relevant species correction factors, i.e. transect width (1000m) divided by (ESW x 2 ) = species correction factor. The area correction factors and species correction factors, adjusted by the relevant effective strip widths, i.e. how far each species is readily seen, is then used to calculate the population estimates. So basically, the area correction factor multiplies the number seen up based on the percentage of the area sampled and assumes all animals within 500 m of the transect line are detected. The species correction factor then adjusts this estimate based on the detection curve (ESW) for the species. The correction factors and route distances as used in the 2015 game count methodology, along with the area represented per zone can be seen in table 5 below.

Table 5. Total count areas per zone (ha), route distances, area correction factors, effective strip widths and species correction factors for each species within each zone for 2020.
Count areas, area correction factors, effective strip widths and species correction
factor for 2020

| :--- | :--- | :--- | :--- |

Figure 1. The game count area shows the ten zones used in May 2020 for the NamibRand Nature Reserve (1-8, 10) and the Pro-Namib Conservancy (9).

In order to determine and show the distribution and density of game in the various zones of the count area, monad grids are used to map the locality of the animals counted. Each route is supplied with a map containing the monad, with reference numbers, of the zone in which that route is set as seen in the image below.

During the count the monad grid number in which animal counted is seen, is recorded. This grid number is then used to map the distribution of each recorded animal.

Figure 2. Monad maps.

## 4. Objectives and results of the May 2020 count:

## Objective 1: Population and biomass estimates

## Population estimates:

The population estimates for individual species in the total count area are derived from the actual number of animals seen during the count and the relevant species and area correction factors that are applied to that number. The actual numbers seen is multiplied by the relevant area and species correction factors to get the population estimates.

S: Actual number of animals seen*
A: Area correction factor

Formula for calculating population estimates* $(\mathrm{S} \times \mathrm{A}) \times \mathrm{B}=\mathrm{P}$

B: Species correction factor
*Known numbers
Note that where total numbers of species with small populations are known (e.g. for recently introduced species such as red hartebeest, Burchell's zebra and giraffe), these known totals are used for the final population estimates in reference to the above calculated estimates.

The total estimates per species per zone were then combined for all zones in order to determine the total population estimate for each plains game species in the count area (see Table 1 below).

Table 1. Total number of game seen and the estimated numbers for May 2020.

Total estimated numbers of game (Zone 1-10; May 2020)

| Species | No. Counted | Estimate 2020 |
| :--- | ---: | ---: |
| Gemsbok | 552 | 6758 |
| Springbok | 571 | 8981 |
| Kudu | 0 | 0 |
| Steenbok | 0 | 0 |
| Ostrich | 76 | 1293 |
| Ludwigs Bustard | 10 | 168 |
| Ruppel's Korhaan | 15 | 984 |
| B. zebra | 152 | 2058 |
| Hartebeest | 1 | 4 |
| Total | $\mathbf{1 3 7 6}$ | $\mathbf{2 0 2 4 2}$ |
| Giraffe* | 10 | 10 |

* Total numbers known

Population estimates are multiplied by the mean weight of the species and divided by the total count area (ha) to get the estimated biomass per species.

E: Estimated wildlife numbers
M: Mean mass per species
H: Total no. of hectares

Formula for calculating biomass estimates
$($ ExM) $\div H=B$

B: Biomass estimate
Biomass estimates are important in terms of managing habitat conditions and inter-specific competition.
Note that agricultural Livestock Units (LSU) are not used for determining the biomass of wildlife species, due to differences between domestic and wild animals. These two species are different in aspects such as grazing/browsing patterns and agricultural stocking. LSU are also in a fenced systems opposed to the open, unfenced system within the Reserve.

Tables 6.1, 6.2 and 6.3 below show the biomass estimates for this year, and the biomass estimates for previous years compared to this year.

Table 6.1 Wildlife biomass estimates for May 2020.

| Total | $\mathbf{5 , 6}$ | $\mathbf{5 , 3}$ | $\mathbf{- 6 . 0 1 \%}$ | $\mathbf{5 . 3}$ | $\mathbf{0 . 0 0 \%}$ |

To calculate the population density, the actual number of animals per species counted in each zone is divided by the respective route length and then multiplied by 100 to get the total number of animals seen per 100 km .

S: Actual number of animals seen
R : Length of route
K: Wildlife density - i.e. Animals seen per 100km driven

Formula for calculating wildlife density $(S \div R) \times 100=K$

For the purposes of this report, wildlife distribution is based on the amount of animals seen in each monad. During the game count, each sighting is marked to the corresponding monad the animal(s) was seen in. This data is then used to map the distribution of the animals (i.e. where animals were seen).

Please note that for the total wildlife distribution, all game species counted were used in the (mapping) calculation. The total wildlife (species) distribution and density are shown in the maps below. These densities were calculated using the formula prescribed above.
Note that the data is indicated on a gradient from light (low values) to dark (high values).

## Objective 3: Population change

The total estimated numbers of game for the May 2019 count is compared to those from previous years to illustrate the population change, and are shown in Tables 10 and 11 below. The overall population estimate has increased by $43 \%$ and the number of animals counted per 100 km per route has increased by $38.42 \%$.

Table 10. Population estimates for 2020 compared to 2019.

| Total estimated numbers of game (Zone 1-10; May 2019 - May 2020) |  |  |  |  |  |

The graphs in figure 7.1-7.4 below, show the total long term individual estimate changes for the four most common species. Please note that the figures of these graphs are taken from the respective species estimates from the maximum number of routes counted in each year.

Figure 7.1

Figure 7.2

Figure 7.3

Figure 7.4

The graph in Figure 8 below shows long term total population estimate change compared to the average annual rainfall received for the same period. Please note that as with the previous graphs, the figure for this graph was taken from the total population estimates and from the maximum number of routes counted in each year.

Figure 8. Total population change 2005 to 2020 compared to average rainfall.

Total population change 2005-2022 compared to rainfall

## 5. Discussion and conclusions

## Gemsbok

Interestingly the number of actual gemsboks seen was lower than than the previous year, the estimated population was higher. This can happen if the animals were closer to the road and therefore easier to see and be certain of the total numbers in each herd. When the species correction factor is applied there is no accounting for any observation error and the estimated population is closer to the actual number counted.

The results of the 2020 gemsbok population estimate show an increase of 94.19\% (6758 gemsbok) from last year's estimate ( 3480 gemsbok).

The highest density of gemsbok was recorded in Zone 6, which had a total of 266 gemsbok per 100 km . The second highest density of gemsbok was in Zone 7 ( 202 gemsbok per 100 km ). The gemsbok was found in every zone of the reserve.

## Springbok

The springbok numbers were higher than the previous year, and the so is the population estimate. The estimated number of springboks for this year is 8981, with an increase of $564.75 \%$ from last year of 1351 . This would be the same reason as with gemsbok, animals closer to the road.

The springbok was predominantly concentrated in Zones 3, 7 and 9. No springbok was recorded for zone 4 and 5. In the other zones significant smaller number of springboks was recorded compared to zone 3,7 and 9 .

## Ostrich

This year's ostrich population estimate is 1293 . This is an $638.60 \%$ increase from last year's population estimate of 175. Most of the sightings were in Zone 9 ( 33 ostrich), same as the previous year followed by zones 10,3 and 6.

## Burchell's Zebra

This year, a total of 152 zebra were counted to give a total estimated population of 2058. They were only counted in zone $2,6,7,8$ and 9 , with zone 6 have the highest density compared to the other zones.

## Red Hartebeest

They were only seen one hartebeest seen in zone 2 , compared to last year when 16 were counted. This is a decrease of 93.31\%.

## Giraffe

There were three giraffes sighted during this year's game count in route 6. However, with regular sightings there are 10 giraffes on the reserve.

## 6. Acknowledgments

The NamibRand Nature Reserve would like to thank all of its concessionaires, stakeholders, neighbors and participants for their enthusiastic involvement to make this year's game count another success.

This year's participants were:
Murray Tindall, Norman, Nils Odendaal, Danica Shaw, Erich Simon, Gert Tsaobeb, Willem Hanse, Amushe Tobias, Michael Kanyanga, Jonas Ndeuludila, Mupiri Thadeus, Salom Haiduwa, Simon Rooi, Abraham Tsaobeb, Thomas Soutschka, Kerstin Klein, Di Wucher, Dierind Basson, Marius Basson, Elizabeth Johannes, Ruben Bonifacio, Martin Verwey, Marlise Verwey, Wian Boshoff, Ettinne, Sanet, Rossouw, Elton Vries, Johannes Benisius, Zazapamue Hange, Abraham Hantenya

## 7. Appendix

## Results per count route per zone

Tables 12.1 to 12.11 list the data collected on each route in May 2019, which were used as a basis for the analysis.
